

# ADHD Research Study

## for Preschool-Age Children

**About This Study:** If your child is 4 to 5 years of age and has attention-deficit/hyperactivity disorder (ADHD), we are inviting you to take part in a research study. The purpose of this study is to evaluate the effectiveness and safety of extended-release viloxazine for ADHD symptoms in preschool-age children compared to a placebo study drug (a drug with no active ingredients that looks like the study drug).

This research study will enroll about 286 children with ADHD at participating study centers throughout the United States.

### What does this research study involve?

Participation in this study will involve 8 clinic visits over the course of about 8 weeks. During visits, you and your child will be asked to answer questions about your child's diagnosis of ADHD, other psychiatric disorders, and your child's thoughts and feelings. Throughout the study, we will assess medical, biological, and behavioral outcomes using things like questionnaires, physical exams, blood draws, vital signs, electrocardiogram (ECG), and urine drug screens.

### Who can participate?

Your child may be eligible to join this study if they:

- Are 4 to 5 years of age
- Have ADHD
  - Symptoms in preschoolers include: excessive talking, hyperactivity, impulsivity, interrupting, losing things, constant fidgeting, difficulty paying attention, being loud/disruptive during activities, etc.
